On the third, at the seventh hour, the stars were arranged in this
 sequence. The eastern one was 1 minute, 30 seconds from Jupiter
 the closest western one 2 minutes; and the other western one was
 3 minutes removed from this one. They were absolutely on the same
 straight line and of equal magnitude.

On the fourth, at the second hour, there were four stars around
 Jupiter, two to the east and two to the west, and arranged precisely
 in a straight line, as in the adjoining figure. The easternmost was
 distant 3 minutes from the next one, while this one was 40 seconds
 from Jupiter; Jupiter was 4 minutes from the nearest western one
 and this one 6 minutes from the westernmost one. Their magnitude
 were nearly equal; the one closest to Jupiter appeared a little smaller
 than the rest. But at the seventh hour the eastern stars were only
 30 seconds apart. Jupiter was 2 minutes from the nearer eastern
 one, while he was 4 minutes from the next western one, and this
 one was 3 minutes from the westernmost one. They were all equal
 and extended on the same straight line along the ecliptic.

On the fifth, the sky was cloudy.

On the sixth, only two stars appeared flanking Jupiter, as is seen
 in the adjoining figure. The eastern one was 2 minutes and the
 western one 3 minutes from Jupiter. They were on the same straight
 line with Jupiter and equal in magnitude.

On the seventh, two stars stood near Jupiter to the east

"Galileo...
is the father of modern physics—indeed of modern science."

— Stephen Hawking quoting Albert Einstein

History of experiments

From Wikipedia, the free encyclopedia

The history of [experimental research](#) is long and varied. Indeed, the definition of an experiment itself has changed in responses to changing norms and practices within particular fields of study. This article documents the history and development of experimental research from its origins in [Galileo's](#) study of gravity into the diversely applied method in use today.

Distance d traveled by an object falling for time t where g is gravitational acceleration ($\sim 9.8 \text{ m/s}^2$):

$$d = \frac{1}{2}gt^2$$

These results supported Galileo's hypothesis that objects of different weights, when measured at the same point in their fall, are falling at the same speed because they experience the same gravitational acceleration.

PREDICTION X

Galileo saw beauty in a world of patterns.

So do I.
